ABSTRACT

Volume tables and equations were derived from a sample of trees from the Kuskokwim River valley. Cubic-foot tables were developed for white spruce, paper birch, and balsam poplar. Board-foot tables, International 1/4-inch and Scribner rules, were prepared for white spruce.

KEYWORDS: Volume tables, volume equations, white spruce, balsam poplar, paper birch, Kuskokwim River valley, Alaska.

INTRODUCTION

Analysis of data obtained during a preliminary timber reconnaissance in the Kuskokwim River valley in 1966 indicated the volume equations developed by Haack^{1/} for interior Alaska did not apply to this area. Therefore, in 1967, when an inventory was made of the forest resources along the Kuskokwim River, 295 trees were felled and measured so that volume equations and tables could be developed. Volume equations and tables derived from these measurements are presented here.

The species sampled were white spruce (*Picea glauca* (Moench) Voss), balsam poplar (*Populus balsamifera* L.), and paper birch (*Betula papyrifera* Marsh.). Sample trees were selected by extending the standard forest inventory 10-point cluster^{2/} to an 11th point. Commercial forest land and operable noncommercial forest land were sampled.^{3/}

Up to three trees 5-inch diameter breast high (d. b. h.) or larger were systematically selected per point. Cull and obviously deformed trees were not included in the sample

The sample trees were felled and measured using procedures similar to those described by Haack.^{4/} Diameter outside bark and double bark thickness were recorded at the 1-foot stump, d. b. h., 9.15 feet on the bole, and then at 8.15-foot intervals to a 4.0-inch diameter outside bark. Measurements were also taken where there were pronounced changes in diameter such as at forks. For spruce sawtimber trees, 9-inch d. b. h. or larger, and hardwood species, 11-inch d. b. h. or larger, measurements were also taken at the minimum saw-log diameter, 7-inch and 9-inch diameter outside bark, respectively.

^{2/} USDA Forest Service, FSH 4813.1 Forest Survey Handbook. p. 42.9--1, March 1967.

^{3/} Sites capable of producing at least 20 cubic feet per acre per year are classified as commercial forest land by Forest Survey, and sites producing less, noncommercial. Noncommercial sites presently supporting 800 or more cubic feet per acre are considered operable noncommercial.

^{4/} Paul M. Haack. Compilation of tree measurement data by hand or computer. Juneau, USDA Forest Serv. Northern Forest Exp. Sta., 17 p., 1964.

Smalian's formula was used to compute cubic-foot volume to a 4-inch diameter outside bark.

International 1/4-inch and Scribner rules were used to compute board-foot volumes for white spruce sawtimber trees from a 1-foot stump to a 7.0-inch diameter outside bark for 16.30-foot^{5/} logs. Partial logs 8.15 feet to 16.30 feet long were treated as full logs. Partial log lengths shorter than 8.15 feet were given zero volume.

These same log rules were used to compute board-foot volumes for birch and poplar sawtimber trees from a 1-foot stump to a 9.0-inch diameter outside bark. Because the sample yielded only 11 birch and 20 poplar sawtimber trees, reliable board-foot volume equations or tables could not be developed. Analysis of the data, however, indicated paper birch in the Kuskokwim River valley has less volume and balsam poplar more volume for a given diameter (D) and total height (H) than reported by Haack^{6/} for the interior of Alaska in general.

Regression analysis was used to develop the volume (V) equations. Equations tested were:

Weighted combined variable,

$$\frac{V}{D^2H} = \frac{b_0}{D^2H} + \frac{b_1}{DH} + \frac{b_2}{H} + \frac{b_3}{D^2} + b_4 + \frac{b_5}{D^4H}$$

Logarithmic combined variable,

$$\log V = \log b_0 + b_1 \log D^2H + b_2 (\log D^2H)^2$$

and the Schumacher logarithmic equation,

$$\log V = \log b_0 + b_1 \log D + b_2 \log H$$

Separate formulas were developed for each species, location (upper and lower Kuskokwim), and land use (commercial and noncommercial forest land) combination. Subsequent tests using analysis of covariance indicated that data from the upper and lower Kuskokwim and from commercial and noncommercial forest land could be pooled. Analysis of covariance also indicated that cubic-foot volume data for balsam poplar and paper birch could be pooled.

^{5/} Includes 0.3-foot trim allowance.

^{6/} See footnote 1.

Relative efficiency of weighted combined vs. the logarithmic regressions was determined in the manner suggested by Furnival.^{7/} In all cases, the weighted combined variable equation reduced to the form:

$$\frac{V}{D^{2H}} = \frac{b_0}{D^{2H}} + b_4$$

and this form of the equation proved more efficient than either of the logarithmic equations. Schumacher's logarithmic equation was second best in all cases.

The basic data used by Haack^{8/} to develop volume tables for interior Alaska were compared with these data by use of analysis of covariance. These tests showed a significant difference between equations for all species-volume combinations.

DISCUSSION

These equations and tables were developed for and used with the forest inventory of the Kuskokwim River valley. They may prove superior to other existing tables for use in other timber stands in western Alaska such as the lower Yukon, Koyukuk, and Kobuk River valleys, but no tests have been made to determine this.

The equations used and their precision are given in footnote 1 of each volume table.
